## Satellite sound circuit with noise reduction

## TDA8741; TDA8741H

## FEATURES

- Demodulation of main audio signal using wide band PLL (lock range selectable)
- Demodulation of secondary audio signals using wide band PLL
- Noise reduction of the secondary audio signals
- Output selection: stereo, language 1, language 2, main audio and external
- Mute control
- Line outputs (SCART level).

## APPLICATIONS

- Satellite receivers
- TV sets
- Video recorders.

## GENERAL DESCRIPTION

The TDA8741; TDA8741H is a multi-function sound IC for use in satellite receivers, television sets and video recorders. The pin numbers given in parenthesis throughout this document refer to the QFP44 package.

## QUICK REFERENCE DATA

### FUNCTIONAL DESCRIPTION

#### Satellite sound

The baseband signal coming from a satellite tuner contains the demodulated video signal plus a number of sound carriers to facilitate reception of a PAL/NTSC/SECAM satellite signal.

Nearest to the video signal is the main sound carrier which carries the single channel sound related to the video. This is an FM modulated carrier with a fixed pre-emphasis. The carrier frequency can be in the range of 5.8 to 6.8 MHz.

Additionally, a number of optional secondary sound carriers may be present which can be used for stereo or multi-language sound related to the video, or for unrelated radio sound. These carriers are also FM modulated, but for better sound quality (improved signal-to-noise performance) broadcast satellites (e.g. 'ASTRA') use a noise reduction system (adaptive pre-emphasis circuit, combined with a fixed pre-emphasis).

These secondary carrier frequencies can be in the range of 6.30 to 8.28 MHz. For accurate tuning to the many sound carriers an external frequency synthesizer and mixer is used to transpose the sound carriers to intermediate frequencies of 10.7 and 10.52 MHz.

The TDA8741; H contains all circuitry for processing the main channel and for two secondary channels, from IF signal to line (SCART) output drivers. The desired frequencies can be routed to the TDA8741; H via bandpass filters.

#### Main channel (see Fig.1)

The lock-in range of the main channel PLL can be switched between 5.5 to 7.5 MHz, PLL off and 10.0 to 11.5 MHz using the MCS signal at pin 7 (2) [when pin 7 (2) is at logic 0, being a voltage from 0 to 1.2 V, the lock-in range = 5.5 to 7.5 MHz; when pin 7 (2) is at logic 1, being a voltage from 3.5 V until  $V_P$ , the lock-in range = 10.0 to 11.5 MHz; when pin 7 (2) is in the mid voltage position, being a voltage from 1.8 to 2.8 V, the main channel PLL is switched off]. The voltage is then determined by the resistor divider at this pin between  $V_P$  and ground.

If only one fixed carrier frequency for the main channel is to be demodulated (e.g. 6.5 MHz), the lock-in range of the PLL should be switched to 5.5 to 7.5 MHz. The baseband signal is applied to the main channel input, pin 18 (14) via a 6.5 MHz ceramic bandpass filter. Alternatively, if there is a requirement to demodulate different main channel frequencies, these frequencies can be transferred to a fixed intermediate frequency (e.g. 10.7 MHz) using an

external mixer and oscillator-frequency synthesizer. In this event the lock-in range of the PLL should be switched to 10.0 to 11.5 MHz. The IF signal is applied to the main channel input, pin 18 (14) via a 10.7 MHz ceramic bandpass filter.

The filtered signal is AC-coupled to a limiter/amplifier and then to a PLL demodulator. The PLL FM demodulator ensures that the demodulator is alignment-free. High gain and DC error signals from the PLL, which are superimposed on the demodulator output, require DC decoupling. A buffer amplifier is used to amplify the signal to the same level as the secondary channels and decouples DC using an electrolytic capacitor connected to pin 41 (37). The demodulator output signal is fed to pin 20 (16) via an internal resistor. The output signal can be de-emphasized by means of this resistor and an external capacitor connected to ground.

Capacitor value = de-emphasis time constant per 1500 (for 50  $\mu$ s: 33 nF).

From here the signal is fed to the output selectors. The signal is amplified to 500 mV (RMS) (i.e. -6 dBV) in the output amplifiers.

#### Secondary channels

An external mixer and oscillator frequency synthesizer transfers the secondary sound carriers to fixed intermediate frequencies e.g. 10.7 and 10.52 MHz. Two secondary channel inputs are available at pins 8 and 16 (3 and 11). The signals are routed to the inputs via external ceramic bandpass filters which are tuned to the required intermediate frequencies.

For stereo applications the TDA8741; TDA8741H contains two identical secondary sound processing channels. Secondary Channel 1 will also be referred to as 'LEFT' or 'LANGUAGE 1' and secondary Channel 2 will also be referred to as 'RIGHT' or 'LANGUAGE 2'.

From the inputs the signals are coupled to limiter/amplifiers and then to the PLL demodulators. Processing is similar to the main channel. The demodulator output signal is amplified in a buffer amplifier and DC decoupled using electrolytic capacitors connected to pins 40 (36) (left) and 42 (38) (right). The output level is set with a resistor connected in series with the capacitor.

High frequency components in the amplified PLL output signal are filtered out in the audio LPF block (4th order Butterworth low-pass filter) to prevent unwanted influence on the noise reduction.

## Satellite sound circuit with noise reduction

## TDA8741; TDA8741H

### NOISE REDUCTION (NR)

The noise reduction can be regarded as an input level-dependent low-pass filter (adaptive de-emphasis system) followed by a fixed de-emphasis. With maximum input level (0 dB) the frequency response of the first part (i.e. without the fixed de-emphasis) is virtually flat. As the input level is lowered by x-dB, the higher output frequencies will be reduced an extra x-dB with respect to the lower frequencies (1 : 2 expansion).

The NR output signal is fed to pin 36 (32) (left) and pin 32 (28) (right) via an internal resistor.

Fixed de-emphasis is achieved by these resistors and external capacitors connected to ground. The signals are DC decoupled via pins 36/35 (32/31) and 32/33 (28/29) and then routed to the output selectors.

### OUTPUT SELECTION

With the output selector (see Table 1) the outputs at pins 25 and 24 (21 and 20) can be switched to the different channels. Both outputs can be switched to both secondary channels, to the main channel and to the external inputs at pin 28 and 27 (24 and 23) for IC chaining purposes.

Pin 23 (19) is a separate output which delivers the main channel only, thereby creating the possibility of having three different output channels simultaneously e.g. for use in hi-fi VCRs.

The outputs at pins 25 and 24 (21 and 20) can be muted by setting the MUTE signal at pin 13 (8) to logic 1 (switch positions 6 and 7).

The output at pin 23 (19) can be muted by setting the MUTE signal and the EXT/INT signal at pin 26 (22) both logic 1 (switch position 7).

All outputs at pins 23, 24 and 25 (19, 20 and 21) are line drivers with SCART level capability and are short-circuit protected by 125  $\Omega$  output resistors.

Output level of all channels = -6 dBV typical when frequency deviation of FM signal is 54% of maximum frequency deviation (i.e.  $0.54 \times 85 \text{ kHz} = 46 \text{ kHz}$  for the main channel and  $0.54 \times 50 \text{ kHz} = 27 \text{ kHz}$  for the secondary channels) at 1 kHz modulation frequency (reference level).

### ABBREVIATIONS

$f_{\text{MOD}}$  = modulating frequency.

$\Delta f_{\text{M}}$  = frequency deviation of the main Channel.

$\Delta f_{\text{S1}}$  = frequency deviation of secondary Channel 1 (left).

$\Delta f_{\text{S2}}$  = frequency deviation of secondary Channel 2 (right).

$f_{\text{OM}}$  = carrier frequency of main Channel.

$f_{\text{OS1}}$  = carrier frequency of secondary Channel 1.

$f_{\text{OS2}}$  = carrier frequency of secondary Channel 2.

LPF = Low-Pass Filter.

NR = Noise Reduction.

PLL = Phase-Locked-Loop.

## Satellite sound circuit with noise reduction

## TDA8741; TDA8741H

**Notes to the AC characteristics**

1. At pin 20 (16) the demodulated 1 kHz signal should be present with a typical level of 158 mV (RMS) (–16 dBV), and THD of maximum 0.5%;  $V_P = 8$  to 13.2 V;  $T_{amb} = -20$  to  $+70$  °C.
2. Modulation of main channel is OFF; modulation of secondary channels is ON.
3. The electrolytic capacitors at pins 40 and 42 (36 and 38) are removed and 1500 pF capacitors between pin 40 (36) and ground and between pin 42 (38) and ground are connected. At pins 40 and 42 (36 and 38) the demodulated 1 kHz signals should be present with typical levels of 9 mV (RMS) and THD of maximum 0.5%;  $V_P = 8$  to 3.2 V;  $T_{amb} = -20$  to  $+70$  °C.
4. All PLLs locked;  $R_{S1} = R_{S2} = 0.68$  k $\Omega$ .
5. Modulation of secondary channel being measured and main channel is OFF; modulation of other secondary channel is ON.
6. Modulation of main channel is ON; modulation of secondary channels is OFF.
7. Measured at pins 38 (34) (left) and 30 (26) (right) and no electrolytic capacitors connected to these pins.

**Table 1** Truth table for output selection (note 1)

SWITCH POSITION	STATE	PIN 15 (10)	PIN 17 (13)	PIN 26 (22)	PIN 13 (8)

Fig.4 Test circuit.

## Satellite sound circuit with noise reduction

## TDA8741; TDA8741H

## APPLICATION INFORMATION

## General

The satellite baseband signal is routed to a mixer to transfer the various secondary channels to fixed intermediate frequencies of 10.7 and 10.52 MHz. Tuning to the required carrier frequencies can be achieved by varying the oscillator frequency e.g. tuning to 7.02 and 7.20 MHz carrier frequencies requires an oscillator frequency of 17.72 MHz and tuning to 7.38 and 7.56 MHz requires an oscillator frequency of 18.08 MHz. The IF signals are routed to the inputs pin 8 and 16 (3 and 11) via 10.7 and 10.52 MHz ceramic bandpass filters. For the secondary channels the bandpass filter terminating resistor is integrated on-chip (330  $\Omega$  typical) thus no external resistors are required.

**MCS pin 7 (2) = logic 0;** (see Fig.5)

The lock-in range of the main channel PLL is 5.5 to 7.5 MHz. For the main channel a ceramic bandpass filter (e.g. 6.5 MHz) is used to filter out the main sound carrier directly from the baseband signal. Simultaneous demodulation of one main channel and various secondary channels is now possible with a minimum of external components. As no bandpass filter terminating resistor for the main channel pin 18 (14) is integrated on-chip, an external resistor is required.

**MCS pin 7 (2) = logic 1;** (see Fig.6)

The lock-in range of the main channel PLL is now 10.0 to 11.5 MHz. The carrier frequency of the main channel is also transferred to a fixed intermediate frequency. In this event the main audio output level should be adjusted to -6 dBV by inserting a 470  $\Omega$  resistor in series with the electrolytic capacitor on pin 41 (37).

**MCS pin 7 (2) = MID position**

The main channel PLL is off if the voltage is between 1.8 and 2.8 V on pin 7 (2). This situation can be obtained by a floating MCS pin if  $V_P$  is between 10.8 and 13.2 V or by forcing this MCS pin to the desired voltage by an external voltage source. In that event  $V_P$  can be in the full range of 8 to 13.2 V. This feature can be used to slightly improve the signal-to-noise ratio of the secondary channels if the main channel is not used.

If simultaneous demodulation of main- and secondary sound carriers is not required, a low cost solution as given in Fig.6 can be considered. One mixer and frequency synthesizer are used to transfer all sound carriers to intermediate frequencies of 10.7 and 10.52 MHz. When the bandwidth of the main channel is larger than the secondary channel bandwidth, a separate (e.g. 10.7 MHz) ceramic filter plus resistors are required for the main channel.

The secondary sound carriers can be demodulated as described above. If e.g. a 6.65 MHz main sound carrier is to be demodulated, this frequency is mixed to 10.7 MHz by tuning the frequency synthesizer to 17.35 MHz. If the synthesizer is tuned to 17.20 MHz a 6.5 MHz main sound carrier can be demodulated. When main sound is to be demodulated and this IF signal is also available on the secondary Channel 1 input the PLLs of the secondary channels can be disabled by making SCD pin 11 (6) HIGH. The output selector should be in position 4 (main sound on all outputs) if output pins 25 and 24 (21 and 20) are used.

For high-end applications the input level of the NR can be adjusted to give optimum performance. 0 dB is the maximum input level which corresponds to the maximum frequency deviation of the incoming FM signal (50 kHz for secondary channels). If the NR input signal is too low (HIGH) the NR will attenuate (favour) the higher audio frequencies too much due to the expansion character. In general: 1 dB error in NR input level will give a 1 dB difference between low (50 Hz) and high (15 kHz) audio frequencies. With  $R_{S1}$  ( $R_{S2}$ ) the input level and so the frequency response of the NR can be adjusted: at **0 dB input level** (which corresponds to a frequency deviation of 50 kHz) the output level of a 15 kHz modulated signal should be 0.25 dB lower than that of an 50 Hz modulated signal.

### SOLDERING

#### Plastic dual in-line packages

##### BY DIP OR WAVE

The maximum permissible temperature of the solder is 260 °C; this temperature must not be in contact with the joint for more than 5 s. The total contact time of successive solder waves must not exceed 5 s.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified storage maximum. If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

##### REPAIRING SOLDERED JOINTS

Apply the soldering iron below the seating plane (or not more than 2 mm above it). If its temperature is below 300 °C, it must not be in contact for more than 10 s; if between 300 and 400 °C, for not more than 5 s.

#### Plastic quad flat packages

##### BY WAVE

During placement and before soldering, the component must be fixed with a droplet of adhesive. After curing the adhesive, the component can be soldered. The adhesive can be applied by screen printing, pin transfer or syringe dispensing.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder bath is 10 s, if allowed to cool to less than 150 °C within 6 s. Typical dwell time is 4 s at 250 °C.

A modified wave soldering technique is recommended using two solder waves (dual-wave), in which a turbulent wave with high upward pressure is followed by a smooth laminar wave. Using a mildly-activated flux eliminates the need for removal of corrosive residues in most applications.

##### BY SOLDER PASTE REFLOW

Reflow soldering requires the solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the substrate by screen printing, stencilling or pressure-syringe dispensing before device placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt, infrared, and vapour-phase reflow. Dwell times vary between 50 and 300 s according to method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 min at 45 °C.

##### REPAIRING SOLDERED JOINTS (BY HAND-HELD SOLDERING IRON OR PULSE-HEATED SOLDER TOOL)

Fix the component by first soldering two, diagonally opposite, end pins. Apply the heating tool to the flat part of the pin only. Contact time must be limited to 10 s at up to 300 °C. When using proper tools, all other pins can be soldered in one operation within 2 to 5 s at between 270 and 320 °C. (Pulse-heated soldering is not recommended for SO packages.)

For pulse-heated solder tool (resistance) soldering of VSO packages, solder is applied to the substrate by dipping or by an extra thick tin/lead plating before package placement.

**DEFINITIONS**

<b>Data sheet status</b>	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
<b>Limiting values</b>	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
<b>Application information</b>	
Where application information is given, it is advisory and does not form part of the specification.	

**LIFE SUPPORT APPLICATIONS**

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
